INFLUENZA IN ADULTS 65+: THE FACTS

Influenza is a highly infectious viral illness. It can cause mild to severe illness, and at times can lead to death.¹

**DISEASE PRESENTATION IN OLDER ADULTS**

The clinical presentation of influenza ranges from asymptomatic infection or a self-limiting upper respiratory tract infection, to a severe illness with potentially fatal complications.¹

In older adults, influenza sometimes presents differently than it does in other age groups:

- Older adults may experience malaise, instead of the sudden onset of high fever typical in children and younger adults.²

- Stomach pain, diarrhea, and nausea are more frequent symptoms in older adults than in other age groups.²

- Runny nose, sore throat, and nasal congestion are all less frequent symptoms in older adults than in other age groups.²

**AN AGING IMMUNE SYSTEM**

Immunosenescence is the biological aging process associated with progressive decline in systemic immunity. This gradual deterioration of the immune system, brought on by natural aging, can cause increased susceptibility to common infectious diseases, including influenza, among older adults.²,³

Additionally, inflamm-aging, a chronic progressive increase in the proinflammatory status of the older adult, contributes to all aging-related diseases and renders older adults more vulnerable to complications as a result of infection with influenza.⁴

**SERIOUS COMPLICATIONS**

Complications from influenza can lead to life-threatening conditions in older adults. Serious complications include¹:

- Pneumonia
- Myocarditis, encephalitis, myositis, or rhabdomyolysis
- Multi-organ failure (e.g., respiratory and kidney failure)
- Respiratory tract infection leading to an extreme inflammatory response and sepsis
ADULTS AGE 65+ YEARS AND OLDER ARE DISPROPORTIONATELY AFFECTED BY THE FLU

Older adults account for about 70%–85% of annual flu-related deaths in the United States.\(^5\)

50%–70% of influenza-related hospitalizations in the U.S. occur among people 65 years and older. For example, in 2017–18, approximately 65% of the estimated 710,000 flu-related hospitalizations were in adults 65 years and older.\(^5,6\)

Older adults experience longer hospital stays than younger adults.\(^7,8\) An extended hospital stay may have a negative impact on their quality of life following discharge.\(^9\)

THOSE LIVING WITH CHRONIC DISEASES

Influenza is dangerous for adults living with chronic diseases such as diabetes and heart and lung conditions.\(^10\)

Many adults remain unaware that they have a chronic disease, and ensuring that they get vaccinated provides a layer of protection for these potentially vulnerable people.

Diabetes
Patients with diabetes are at a higher risk of severe outcomes than other people.\(^11,12\)

Heart conditions
Patients with heart disease, or those who had a stroke, have a higher risk of serious complications from influenza, including myocarditis, inflammation of muscle tissues, heart attack, and multi-organ failure.\(^10,11,13\)

Lung conditions
Patients with chronic obstructive pulmonary disease (COPD), asthma, or other lung conditions also have a higher risk of complications from influenza. Since people with these conditions have sensitive airways, inflammation caused by the flu can make COPD symptoms worse, trigger asthma attacks, and easily lead to the development of pneumonia and other respiratory diseases.\(^11,12\)

POSSIBLE LONG-TERM IMPACT

Even when they recover from the flu, older adults may never fully regain their pre-influenza health, abilities, and lifestyle.\(^9\) Moreover, for months after getting the flu, older adults may still be at increased risk of cardiovascular problems such as heart attack or stroke, due to lingering inflammation and an increased risk of blood clots associated with infections like influenza.\(^2\)
